Output Details

- Output Compatibility CMOS
- Drive Capability 15pF
- CMOS input and output levels:
Input/Output High: 2.4V min
Input/Output Low: 0.4V max
- 1PPS Output (pin 5):
Pulse width: 100ms typ
Accuracy (synchronizing with 1PPS reference): ± 50 ns max
Holdover ($\Delta T = \pm 10^\circ\text{C}$, 8 hours holdover after power up for 7 days; temperature slope less than 2°C per minute) $\pm 1.5\mu\text{s}$ max
- 10MHz Output (pin 6): CMOS
- State Input (pin 1): the clock module synchronizes its local clock to a reference input such as 1PPS from GPS. It will perform normal synchronization algorithm when the state input pin is driven high. It can also be forced to work in free-run or holdover status when the state input pin is driven low. Note: pin 1 (state-input) must be asserted 'high' or 'low' and should not be left unconnected.
- Lock Status:
Indicates the lock status of the clock module. High level indicates the module is locked to the external 1PPS reference. After power-up and before the module locks to 1PPS input, the status of the module is in 'free-run' and the lock output is low. If the 1PPS reference is lost, the module switches to holdover mode and the lock output is low.

Output Control

- UART: is an LVTTTL-compatible port and needs an external translator to work with other signal types (such as RS-232C or RS-485).
- UART Serial Interface (Pins 8 & 9)
Baud rate: 115200
Data bits: 8
Parity: N
Stop Bits: 1
- UART Tx: Data word output in sync with 1PPS output.
